

TITLE OF THE INVENTION
HIV INTEGRASE INHIBITORS

5 This application claims the benefit of U.S. Provisional Application Nos. 60/551,625 (filed March 9, 2004) and 60/633,134 (filed December 3, 2004), the disclosures of which are hereby incorporated by reference in their entireties.

FIELD OF THE INVENTION

10 The present invention is directed hydroxy tetrahydro-2,6-naphthyridine dione and hydroxy hexahydro-2,6-naphthyridine dione compounds and pharmaceutically acceptable salts thereof, their synthesis, and their use as inhibitors of the HIV integrase enzyme. The compounds and pharmaceutically acceptable salts thereof of the present invention are useful for preventing or treating infection by HIV and for preventing or treating or delaying the onset of AIDS.

15 BACKGROUND OF THE INVENTION

A retrovirus designated human immunodeficiency virus (HIV), particularly the strains known as HIV type-1 (HIV-1) virus and type-2 (HIV-2) virus, is the etiological agent of the complex disease that includes progressive destruction of the immune system (acquired immune deficiency syndrome; AIDS) and degeneration of the central and peripheral nervous system. This virus was previously known as LAV, HTLV-III, or ARV. A common feature of retrovirus replication is the insertion by virally-encoded integrase of +proviral DNA into the host cell genome, a required step in HIV replication in human T-lymphoid and monocytoid cells. Integration is believed to be mediated by integrase in three steps: assembly of a stable nucleoprotein complex with viral DNA sequences; cleavage of two nucleotides from the 3' termini of the linear proviral DNA; covalent joining of the recessed 3' OH termini of the proviral DNA at a staggered cut made at the host target site. The fourth step in the process, repair synthesis of the resultant gap, may be accomplished by cellular enzymes.

20 Nucleotide sequencing of HIV shows the presence of a pol gene in one open reading frame [Ratner, L. et al., Nature, 313, 277(1985)]. Amino acid sequence homology provides evidence that the pol sequence encodes reverse transcriptase, integrase and an HIV protease [Toh, H. et al., EMBO J. 4, 1267 (1985); Power, M.D. et al., Science, 231, 1567 (1986); Pearl, L.H. et al., Nature, 329, 351 (1987)]. All three enzymes have been shown to be essential for the replication of HIV.

30 It is known that some antiviral compounds which act as inhibitors of HIV replication are effective agents in the treatment of AIDS and similar diseases, including reverse transcriptase inhibitors such as azidothymidine (AZT) and efavirenz and protease inhibitors such as indinavir and nelfinavir. The

compounds of this invention are inhibitors of HIV integrase and inhibitors of HIV replication. The inhibition of integrase in vitro and HIV replication in cells is a direct result of inhibiting the strand transfer reaction catalyzed by the recombinant integrase in vitro in HIV infected cells. The particular advantage of the present invention is highly specific inhibition of HIV integrase and HIV replication.

Additional embodiments of the invention include the pharmaceutical compositions, combinations and methods set forth in (a)-(n) above and the uses set forth in the preceding paragraph, wherein the compound of the present invention employed therein is a compound of one of the embodiments, aspects, classes, sub-classes, or features of the compounds described above. In all of these embodiments, the compound may optionally be used in the form of a pharmaceutically acceptable salt.

As used herein, the term "alkyl" refers to any linear or branched chain alkyl group having a number of carbon atoms in the specified range. Thus, for example, "C₁₋₆ alkyl" (or "C₁-C₆ alkyl") refers to all of the hexyl alkyl and pentyl alkyl isomers as well as n-, iso-, sec- and t-butyl, n- and isopropyl, ethyl and methyl. As another example, "C₁₋₄ alkyl" refers to n-, iso-, sec- and t-butyl, n- and isopropyl, ethyl and methyl.

The term "alkylene" refers to any linear or branched chain alkylene group (or alternatively "alkanediyl") having a number of carbon atoms in the specified range. Thus, for example, "-C₁₋₆ alkylene-" refers to any of the C₁ to C₆ linear or branched alkenes. A class of alkenes of particular interest with respect to the invention is -(CH₂)₁₋₆-, and sub-classes of particular interest include -(CH₂)₁₋₄-, -(CH₂)₁₋₃-, -(CH₂)₁₋₂-, and -CH₂-. Also of interest is the alkylene -CH(CH₃)-.

The term "alkylenedioxy" refers to -O-R-O wherein R is (CH₂)₁₋₃ in which one of the hydrogens on each methylene is optionally replaced with C₁₋₄ alkyl. R is preferably (CH₂)₁₋₂ or CH(CH₃), and is more preferably (CH₂)₁₋₂.

The terms "C(O)" and "C(=O)" are alternative representations of carbonyl. The terms "S(O)₂" and "SO₂" are alternative representations of sulfonyl.

The terms "cycloalkyl" refers to any cyclic ring of an alkane having a number of carbon atoms in the specified range. Thus, for example, "C₃₋₈ cycloalkyl" (or "C₃-C₈ cycloalkyl") refers to cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, cycloheptyl, and cyclooctyl.

The term "halogen" (or "halo") refers to fluorine, chlorine, bromine and iodine (alternatively referred to as fluoro, chloro, bromo, and iodo).

The term "haloalkyl" refers to an alkyl group as defined above in which one or more of the hydrogen atoms has been replaced with a halogen (i.e., F, Cl, Br and/or I). Thus, for example, "C₁₋₆ haloalkyl" (or "C₁-C₆ haloalkyl") refers to a C₁ to C₆ linear or branched alkyl group as defined above

with one or more halogen substituents. The term "fluoroalkyl" has an analogous meaning except that the halogen substituents are restricted to fluoro. Suitable fluoroalkyls include the series $(\text{CH}_2)_0\text{-4CF}_3$ (i.e., trifluoromethyl, 2,2,2-trifluoroethyl, 3,3,3-trifluoro-n-propyl, etc.).

5 The term "C₄₋₇ azacycloalkyl" (or "C₄-C₇ azacycloalkyl") means a saturated cyclic ring consisting of one nitrogen and from four to seven carbon atoms (i.e., pyrrolidinyl, piperidinyl, azepanyl, or octahydroazocinyl).

The term "C₃₋₆ diazacycloalkyl" (or "C₃-C₆ diazacycloalkyl") means a saturated cyclic ring consisting of two nitrogens and from three to six carbon atoms (e.g., imidazolidinyl, pyrazolidinyl, or piperazinyl).

10 Unless expressly stated to the contrary, all ranges cited herein are inclusive. For example, a heterocyclic ring described as containing from "1 to 4 heteroatoms" means the ring can contain 1, 2, 3 or 4 heteroatoms. It is also to be understood that any range cited herein includes within its scope all of the sub-ranges within that range. Thus, for example, a heterocyclic ring described as containing from "1 to 4 heteroatoms" is intended to include as aspects thereof, heterocyclic rings
15 containing 2 to 4 heteroatoms, 3 or 4 heteroatoms, 1 to 3 heteroatoms, 2 or 3 heteroatoms, 1 or 2 heteroatoms, 1 heteroatom, 2 heteroatoms, and so forth.

When any variable (e.g., R^a, R^b, or HetA) occurs more than one time in any constituent or in Formula I or in any other formula depicting and describing compounds of the invention, its definition on each occurrence is independent of its definition at every other occurrence. Also,
20 combinations of substituents and/or variables are permissible only if such combinations result in stable compounds.

The term "substituted" (e.g., as in "is optionally substituted with from 1 to 5 substituents ...") includes mono- and poly-substitution by a named substituent to the extent such single and multiple substitution (including multiple substitution at the same site) is chemically allowed. Unless expressly
25 stated to the contrary, substitution by a named substituent is permitted on any atom in a ring (e.g., aryl, a heteroaromatic ring, or a saturated heterocyclic ring) provided such ring substitution is chemically allowed and results in a stable compound.

Any of the various carbocyclic and heterocyclic rings and ring systems defined herein may be attached to the rest of the compound at any ring atom (i.e., any carbon atom or any heteroatom)
30 provided that a stable compound results. Suitable 5- or 6-membered heteroaromatic rings include, for example, pyridyl, pyrrolyl, pyrazinyl, pyrimidinyl, pyridazinyl, triazinyl, thienyl, furanyl, imidazolyl, pyrazolyl, triazolyl, tetrazolyl, oxazolyl, isooxazolyl, oxadiazolyl, oxatriazolyl, thiazolyl, isothiazolyl, and thiadiazolyl. The foregoing are representative of heteroaromatics defined by HetB and HetL, and included in the definitions of HetC and HetD. Suitable heteroaryls consisting of an aryl fused with a 5-

or 6-membered heteroaromatic ring include, for example, benzopiperidinyl, benzisoxazolyl, benzoxazolyl, chromenyl, quinolinyl, isoquinolinyl, cinnolinyl, and quinazolinyl. The foregoing are representative of fused bicyclic heteroaryls included in the definition of HetC and of fused aryl in part (A) of the definition of R^J. Suitable 4- to 7-membered saturated heterocyclics include, for example, azetidiny, piperidinyl, morpholinyl, thiomorpholinyl, thiazolidinyl, isothiazolidinyl, oxazolidinyl, isoxazolidinyl, pyrrolidinyl, imidazolidinyl, piperazinyl, tetrahydrofuranyl, tetrahydrothienyl, pyrazolidinyl, hexahydropyrimidinyl, thiazinanyl, thiazepanyl, thiadiazepanyl, dithiazepanyl, azepanyl, diazepanyl, thiadiazinanyl, tetrahydropyranyl, tetrahydrothiopyranyl, and dioxanyl. The foregoing are representative of saturated heterocyclics defined by HetK and included in the definition of HetD.

A "stable" compound is a compound which can be prepared and isolated and whose structure and properties remain or can be caused to remain essentially unchanged for a period of time sufficient to allow use of the compound for the purposes described herein (e.g., therapeutic or prophylactic administration to a subject).

As a result of the selection of substituents and substituent patterns, certain of the compounds of the present invention can have asymmetric centers and can occur as mixtures of stereoisomers, or as individual diastereomers, or enantiomers. All isomeric forms of these compounds, whether isolated or in mixtures, are within the scope of the present invention.

As would be recognized by one of ordinary skill in the art, certain of the compounds of the present invention can exist as tautomers, such as the following:

For the purposes of the present invention a reference herein to a compound of Formula I, II, or III is a reference to the compound per se, or to any one of its tautomers per se, or to mixtures of two or more tautomers.

In instances where a hydroxy (-OH) substituent(s) is(are) permitted on a heteroaromatic ring and keto-enol tautomerism is possible, it is understood that the substituent might in fact be present, in whole or in part, in the keto form, as exemplified here for a hydroxypyridinyl substituent:

- 5 Compounds of the present invention having a hydroxy substituent on a carbon atom of a heteroaromatic ring are understood to include compounds in which only the hydroxy is present, compounds in which only the tautomeric keto form (i.e., an oxo substituent) is present, and compounds in which the keto and enol forms are both present.

10 Certain of the compounds of the present invention can exhibit a chirality resulting from the presence of bulky substituents that hinder the otherwise free rotation about a bond. These rotational enantiomers are named atropisomers, and the interconversion can be sufficiently slow to allow for their separation and characterization. See, e.g., J. March, Advanced Organic Chemistry, 4th Edition, John Wiley & Sons, 1992, pp. 101-102; and Ahmed et al., *Tetrahedron* 1998, 13277. For example, certain of the compounds of the present invention in which R⁴ is -C(=O)N(R^a)R^b or -N(R^a)SO₂R^b where at least one of R^a and R^b is alkyl can have sufficiently hindered rotation along the bond linking R⁴ to the bicyclic core of the molecule when R⁵ is other than H (e.g., R⁵ = alkyl, cycloalkyl, or aryl) to permit separation of the enantiomers using, e.g., column chromatography on a chiral stationary phase. The present invention includes atropisomers of compounds embraced by Formula I, singly and in mixtures.

20 The compounds of the present inventions are useful in the inhibition of HIV integrase (e.g., HIV-1 integrase), the prevention or treatment of infection by human immunodeficiency virus (HIV) and the prevention, treatment or the delay in the onset of consequent pathological conditions such as AIDS. Preventing AIDS, treating AIDS, delaying the onset of AIDS, or preventing or treating infection by HIV is defined as including, but not limited to, treatment of a wide range of states of HIV infection: AIDS, ARC (AIDS related complex), both symptomatic and asymptomatic, and actual or potential exposure to HIV. For example, the compounds of this invention are useful in treating infection by HIV after suspected past exposure to HIV by such means as blood transfusion, exchange of body fluids, bites, accidental needle stick, or exposure to patient blood during surgery.

25 The compounds of this invention are useful in the preparation and execution of screening assays for antiviral compounds. For example, the compounds of this invention are useful for isolating enzyme mutants, which are excellent screening tools for more powerful antiviral compounds.

30

Furthermore, the compounds of this invention are useful in establishing or determining the binding site of other antivirals to HIV integrase, e.g., by competitive inhibition. Thus the compounds of this invention are commercial products to be sold for these purposes.

5 The compounds of the present invention may be administered in the form of pharmaceutically acceptable salts. The term "pharmaceutically acceptable salt" refers to a salt which possesses the effectiveness of the parent compound and which is not biologically or otherwise undesirable (e.g., is neither toxic nor otherwise deleterious to the recipient thereof). Suitable salts include acid addition salts which may, for example, be formed by mixing a solution of the compound of the present invention with a solution of a pharmaceutically acceptable acid such as hydrochloric acid, 10 sulfuric acid, acetic acid, trifluoroacetic acid, or benzoic acid. Many of the compounds of the invention carry an acidic moiety, in which case suitable pharmaceutically acceptable salts thereof can include alkali metal salts (e.g., sodium or potassium salts), alkaline earth metal salts (e.g., calcium or magnesium salts), and salts formed with suitable organic ligands such as quaternary ammonium salts. Also, in the case of an acid (-COOH) or alcohol group being present, pharmaceutically acceptable esters can be employed to 15 modify the solubility or hydrolysis characteristics of the compound.

The term "administration" and variants thereof (e.g., "administering" a compound) in reference to a compound of the invention mean providing the compound or a prodrug of the compound to the individual in need of treatment. When a compound of the invention or a prodrug thereof is provided in combination with one or more other active agents (e.g., antiviral agents useful for treating HIV 20 infection or AIDS), "administration" and its variants are each understood to include concurrent and sequential provision of the compound or prodrug and other agents.

As used herein, the term "composition" is intended to encompass a product comprising the specified ingredients, as well as any product which results, directly or indirectly, from combining the specified ingredients.

25 By "pharmaceutically acceptable" is meant that the ingredients of the pharmaceutical composition must be compatible with each other and not deleterious to the recipient thereof.

The term "subject" (alternatively referred to herein as "patient") as used herein refers to an animal, preferably a mammal, most preferably a human, who has been the object of treatment, observation or experiment.

30 The term "effective amount" as used herein means that amount of active compound or pharmaceutical agent that elicits the biological or medicinal response in a tissue, system, animal or human that is being sought by a researcher, veterinarian, medical doctor or other clinician. In one embodiment, the effective amount is a "therapeutically effective amount" for the alleviation of the symptoms of the disease or condition being treated. In another embodiment, the effective amount is a

"prophylactically effective amount" for prophylaxis of the symptoms of the disease or condition being prevented. The term also includes herein the amount of active compound sufficient to inhibit HIV integrase and thereby elicit the response being sought (i.e., an "inhibition effective amount"). When the active compound (i.e., active ingredient) is administered as the salt, references to the amount of active ingredient are to the free acid or free base form of the compound.

For the purpose of inhibiting HIV integrase, preventing or treating HIV infection or preventing, treating or delaying the onset of AIDS, the compounds of the present invention, optionally in the form of a salt, can be administered by any means that produces contact of the active agent with the agent's site of action. They can be administered by any conventional means available for use in conjunction with pharmaceuticals, either as individual therapeutic agents or in a combination of therapeutic agents. They can be administered alone, but typically are administered with a pharmaceutical carrier selected on the basis of the chosen route of administration and standard pharmaceutical practice. The compounds of the invention can, for example, be administered orally, parenterally (including subcutaneous injections, intravenous, intramuscular, intrasternal injection or infusion techniques), by inhalation spray, or rectally, in the form of a unit dosage of a pharmaceutical composition containing an effective amount of the compound and conventional non-toxic pharmaceutically-acceptable carriers, adjuvants and vehicles. Liquid preparations suitable for oral administration (e.g., suspensions, syrups, elixirs and the like) can be prepared according to techniques known in the art and can employ any of the usual media such as water, glycols, oils, alcohols and the like. Solid preparations suitable for oral administration (e.g., powders, pills, capsules and tablets) can be prepared according to techniques known in the art and can employ such solid excipients as starches, sugars, kaolin, lubricants, binders, disintegrating agents and the like. Parenteral compositions can be prepared according to techniques known in the art and typically employ sterile water as a carrier and optionally other ingredients, such as a solubility aid. Injectable solutions can be prepared according to methods known in the art wherein the carrier comprises a saline solution, a glucose solution or a solution containing a mixture of saline and glucose. Further description of methods suitable for use in preparing pharmaceutical compositions of the present invention and of ingredients suitable for use in said compositions is provided in Remington's Pharmaceutical Sciences, 18th edition, edited by A. R. Gennaro, Mack Publishing Co., 1990.

The compounds of this invention can be administered orally in a dosage range of about 0.001 to about 1000 mg/kg of mammal (e.g., human) body weight per day in a single dose or in divided doses. One preferred dosage range is about 0.01 to about 500 mg/kg body weight per day orally in a single dose or in divided doses. Another preferred dosage range is about 0.1 to about 100 mg/kg body weight per day orally in single or divided doses. For oral administration, the compositions can be provided in the form of tablets or capsules containing about 1.0 to about 500 milligrams of the active

ingredient, particularly 1, 5, 10, 15, 20, 25, 50, 75, 100, 150, 200, 250, 300, 400, and 500 milligrams of the active ingredient for the symptomatic adjustment of the dosage to the patient to be treated. The specific dose level and frequency of dosage for any particular patient may be varied and will depend upon a variety of factors including the activity of the specific compound employed, the metabolic
5 stability and length of action of that compound, the age, body weight, general health, sex, diet, mode and time of administration, rate of excretion, drug combination, the severity of the particular condition, and the host undergoing therapy. As an example, the title compound of Example 12 below can be administered to adult humans in the form of an amorphous Na salt in a neat drug-filled capsule in an amount of from about 5 mg to about 800 mg (e.g., 400 mg) twice/day. As another example, the
10 crystalline compound of Example 13 or an amorphous Na salt thereof can be administered to adult humans in the same fashion.

As noted above, the present invention is also directed to use of the HIV integrase inhibitor compounds of the present invention with one or more agents useful in the treatment of HIV infection or AIDS. For example, the compounds of this invention may be effectively administered,
15 whether at periods of pre-exposure and/or post-exposure, in combination with effective amounts of one or more HIV/AIDS antivirals, immunomodulators, anti-infectives, or vaccines useful for treating HIV infection or AIDS, such as those disclosed in Table 1 of WO 01/38332 or in the Table in WO 02/30930. Suitable HIV/AIDS antivirals for use in combination with the compounds of the present invention include, for example, HIV protease inhibitors (e.g., indinavir, atazanavir, lopinavir optionally with
20 ritonavir, saquinavir, or nelfinavir), nucleoside HIV reverse transcriptase inhibitors (e.g., abacavir, lamivudine (3TC), zidovudine (AZT), or tenofovir), and non-nucleoside HIV reverse transcriptase inhibitors (e.g., efavirenz or nevirapine). It will be understood that the scope of combinations of the compounds of this invention with HIV/AIDS antivirals, immunomodulators, anti-infectives or vaccines is not limited to the foregoing substances or to the list in the above-referenced Tables in WO 01/38332
25 and WO 02/30930, but includes in principle any combination with any pharmaceutical composition useful for the treatment of AIDS. The HIV/AIDS antivirals and other agents will typically be employed in these combinations in their conventional dosage ranges and regimens as reported in the art, including, for example, the dosages described in the Physicians' Desk Reference, 57th edition, Thomson PDR, 2003. The dosage ranges for a compound of the invention in these combinations are the same as those set forth
30 above.

The compounds of the present invention can be readily prepared according to the following reaction schemes and examples, or modifications thereof, using readily available starting materials, reagents and conventional synthesis procedures. In these reactions, it is also possible to make use of variants which are themselves known to those of ordinary skill in this art, but are not mentioned in greater detail. Furthermore, other methods for preparing compounds of the invention will be readily apparent to the person of ordinary skill in the art in light of the following reaction schemes and examples. Unless otherwise indicated, all variables are as defined above.

Scheme 1 depicts a method for preparing 5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate intermediates useful for making compounds of the present invention. In the scheme, lactam 1-1 can be alkylated with an appropriate alkyl halide to give 1-2, using methods as described in Jerry March, Advanced Organic Chemistry, 3rd edition, John Wiley & Sons, 1985, pp. 377-379. Piperidin-2-one 1-2 can be converted to the corresponding dihydropyridinone compound 1-5 following the two step procedure set forth in Meyers et al., *Tett. Lett.* 1995, 36: 7051-7054, wherein the lactam can be treated with base and methyl benzene sulfinat to give intermediate 1-4, which can then be treated by heating in a high boiling solvent (e.g., toluene) and optionally in the presence of base to effect the elimination to 1-5. Separately, oxazoles of the type 1-9 can readily be prepared by acylating amino acid ester 1-6 with an oxylate ester 1-7 in the presence of base to afford acylated compound 1-8, which can then be cyclized and dehydrated (using, e.g., P₂O₅) in the manner described in Krapcho et al. *J. Heterocyclic Chem.* 1995, 32, 1693-1702 to afford oxazole 1-9. Diels-Alder reaction of 1-9 and 1-5, optionally in the presence of water or an acid (preferably in the presence of water), will then provide the desired naphthyridine intermediate 1-10.

SCHEME 1

Scheme 2 depicts a method for preparing naphthyridine carboxylates and carboxamides embraced by the present invention from naphthyridine intermediate **1-10**, wherein the intermediate **1-10**

is contacted with a suitable oxidizing agent (e.g., hydrogen peroxide or mCPBA) to obtain N-oxide **2-1**, which can then be treated as described Suzuki et al. *J. Med. Chem.* 1992, 35, 4045-4053 with acetic anhydride to effect the rearrangement to the O-acylated intermediate, and then treated with a nucleophile (e.g., an alkoxide such as NaOMe) to afford the desired dioxohexahydro-2,6-naphthyridine-1-carboxylate **2-2**. The alkyl carboxylate **2-2** can then be further treated with an appropriate amine and trimethylaluminum in the manner described in Evans et al., *J. Am. Chem. Soc.* 1990, 112: 7001 to give the desired alkyl carboxamide **2-3**.

SCHEME 2

Scheme 3 depicts an alternative method for preparing naphthyridine carboxamides **2-3** and analogs in which the R^5 substituent is other than H. The intermediate **2-2** can be alkylated with an alkylating agent (e.g., an alkyl halide or an alkyl sulfate such as dimethyl sulfate) using a suitable base (e.g., (i) an alkali metal carbonate such as K_2CO_3 or Cs_2CO_3 , (ii) an alkali metal hydride such as NaH , (iii) a metal alkoxide such as $Mg(OMe)_2$, or (iv) the combination of (i) and (iii) in successive steps) to give a mixture of N- and O-alkylated products **3-1** and **3-2**. A similar method using alkali metal carbonates is described in T. Ukita et.al., *Chem. Pharm. Bull.* 2000, 48 (4): 589-591. Analogs possessing a non-H R^5 substituent can also be prepared by hydrolysis of the N-alkylated product **3-1** with a nucleophile such as hydroxide to afford the acid **3-3**, followed by conversion to the acid chloride **3-4** using a suitable agent like thionyl chloride or oxalyl chloride/catalytic DMF, similar to the method

described in Jerry March, *Advanced Organic Chemistry*, 3rd edition, John Wiley & Sons, 1985, pp. 388. The acid **3-3** can be coupled with an amine using a peptide coupling reagent such as BOP, or, alternatively, the acid chloride **3-4** can be treated directly with an amine to give the amide. The O-alkylated groups can then be removed under acidic conditions (e.g., using a strong acid like HBr in a suitable solvent like acetic or propionic acid, or using p-toluene sulfonic acid, or a reagent like BBr₃) to give **3-5**, similar to the method described in Jerry March, *Advanced Organic Chemistry*, 3rd edition, John Wiley & Sons, 1985, pp. 384. A similar sequence of hydrolysis, acid chloride formation, coupling and de-protection, starting from the bis-O-alkylated compound **3-2**, can allow the preparation of compounds **2-3**.

SCHEME 3

Scheme 4 depicts a method for preparing compounds of the invention in which the R⁴ group is linked to the parent template via a nitrogen-carbon bond. Acid chloride **3-4** can be treated with sodium azide to give the acyl azide, which will undergo Curtius rearrangement followed by hydrolysis to the amine **4-2**, similar to the method described in R.J. Borchis et.al. *J. Med. Chem.* (1981), 24, 1518-

1521. The amine may then be acylated or sulfonylated with the appropriate agent like an acyl or sulfonyl anhydride or acyl or sulfonyl chloride to give the mono or bis N-acyl or N-sulfonylated intermediate, which can then be converted to product **4-3** by using a suitable nucleophile like sodium methoxide or sodium hydroxide. The amine can further be modified by alkylation with a suitable alkyl halide under the influence of a base (e.g., Cs_2CO_3 or K_2CO_3 , using a method similar to that described in A. Nadin, et.al. *J. Org. Chem.* (2003), 68(7), 2844-2852, to give compounds **4-4**. The O-alkyl group can then be removed with a strong acid like HBr to give **4-5**.

SCHEME 4

Scheme 5 depicts an alternative sequence of transformations similar to those described in the above schemes. Starting with the intermediate **1-10**, O-alkylation, hydrolysis of the ester to the acid,

acid chloride formation, acyl azide formation, Curtius rearrangement and hydrolysis give the intermediate **5-1**, which can be derivatized with various acyl or sulfonyl halides, and then alkylated to give **5-2**. N-oxide formation, similar to that described in M. Adamczyk, *Tetrahedron* (2002) 58, 6951-6963, followed by rearrangement in acetic anhydride and hydrolysis will give **5-4**, and cleavage of the O-alkyl group in acid will afford **5-5**.

SCHEME 5

10 Scheme 6 depicts a route to compounds containing a double bond in the "a" position. These analogs can be prepared from treatment of an intermediate like **1-10** with a brominating agent (e.g., NBS) followed by elimination to give the double bond, similar to the method described in Jerry March, *Advanced Organic Chemistry*, 3rd edition, John Wiley & Sons, 1985, pp. 914. The intermediate

6-1 can then be taken through a series of transformations as previously outlined to give products 6-2 and 6-3.

SCHEME 6

5

Scheme 7 shows methods that can be used to prepare analogs in which R⁴ is attached by a carbon-carbon bond. The amine 4-2 or 5-1 can be converted to the halide 7-1, using methods described in A. Bouillon et.al. *Tetrahedron* 58 (14) 2885-2890 (2002), which will allow for carbon-carbon bond formation. Treatment of the halide with a palladium catalyst and vinyl halide, for example, using methods developed by R. F. Heck (M. Schlosser, *Organometallics in Synthesis, a Manual* 2nd ed. John Wiley and Sons, Ltd. NY 2002, pp 1169) can provide intermediate 7-2, which can be reduced to the alkyl analog 7-3. Similarly, treatment of the halide with an organometallic catalyst such as zinc or palladium and an aryl or heteroaryl boronic acid, an aryl or heteroaryl tin reagent, or an aryl and heteroaryl halide will afford the product 7-4. Such transformations are well known in the art and are described, for example, in J.J. Li, G.W. Gribble *Palladium in Heterocyclic Chemistry*, Pergamon Press NY 2000. Compounds 7-3 and 7-4 can then be taken through the sequence of steps elaborated in previous schemes to afford additional compounds of the present invention.

SCHEME 7

Scheme 8 depicts a method for preparing analogs with R^1 substituents from starting substrate **8-1** with a removable R^* group. Substrate **8-1**, containing an R^* functional group (i.e., a group which is readily removable from an amide moiety, such as p-methoxybenzyl, 3,4- or 2,4-bismethoxybenzyl, allyl, or tosyl), can be prepared by coupling a suitable acid **3-3** or acid chloride **3-4** with an amine (see Scheme 3), and can be de-protected with a strong acid like p-toluene sulfonic acid in a manner similar to the method described in W.M. Kan et.al., *Tetrahedron* 2000, **44**: 1039-1041 to give intermediate **8-2**. Deprotected compound **8-2** can then be bis-alkylated with a suitable alkyl halide using a base (e.g., NaH) to give the N,O-alkylated intermediate **8-3**. Removal of the O-alkyl group with strong acid (e.g., HBR in a solvent such as acetic or propionic acid) will then afford the product **8-4**.

SCHEME 8

Scheme 9 depicts an alternative method for preparing naphthyridine carboxamide analog intermediate **8-1** embraced by the present invention in which the amide substituent is incorporated early in the reaction scheme, and in which the R* substituent (defined in Scheme 8) is used to allow variation of R¹ at a late stage in the synthesis. Starting material **9-1** can be prepared in a manner similar to that used for **1-10**, incorporating the removable group in the initial alkylation step as described for **1-2**. The phenolic group in **9-1** can be protected with a suitable alkyl protecting group (e.g., an R⁵ group as defined herein other than H) followed by hydrolysis with a nucleophile such as hydroxide to afford **9-2**. Protection can be accomplished, for example, by treatment with a diazomethane reagent (e.g., TMS diazomethane) in solvent (e.g., chloroform) or by alkylation with an alkylating agent (e.g., by contact with an alkyl halide or an alkyl sulfate such as dimethyl sulfate) in the presence of a suitable base (e.g., an alkali metal carbonate such as K₂CO₃ or Cs₂CO₃ or an alkali metal hydride such as NaH) in a solvent such as DMSO or methylene chloride. The acid **9-2** can be coupled with an amine using a peptide coupling reagent such as EDC to obtain **9-3**. The intermediate **9-3** can then be treated with a suitable oxidizing agent (e.g., mCPBA or peracetic acid) to obtain the N-oxide, which can then be treated as described Suzuki et al. *J. Med. Chem.* 1992, 35, 4045-4053 with acetic anhydride to effect the rearrangement to the O-acylated intermediate, and then treated with a nucleophile (e.g., an alkoxide such as NaOMe) to afford the dioxohexahydro-2,6-naphthyridine-1-carboxylate **9-4**. Intermediate **9-4** can be alkylated with an alkylating agent (e.g., an alkyl halide or an alkyl sulfate such as dimethyl sulfate) using a suitable base (e.g., an alkali metal carbonate such as K₂CO₃ or Cs₂CO₃, an alkali metal hydride such as NaH, or a metal alkoxide such as Mg(OMe)₂) in a solvent like DMSO to give a mixture of N- and O-alkylated products **8-1** and **9-5**. A similar use of alkali metal carbonates is described in T. Ukita, et.al. *Chem. Pharm. Bull.* 2000, 48 (4) 589-591.

When R* is a benzyl analog containing a chloro in the benzyl ring the chloro can be removed via catalytic dechlorination (e.g., in the presence of 10% palladium on charcoal in methanol) under an atmosphere of hydrogen using conditions similar to those described in M. Freifelder, Catalytic Hydrogenation in Organic Synthesis Procedures and Commentary, John Wiley & Sons, 1978, pp. 121. See, e.g., Examples 69 and 70.

When R* is a benzyl analog, the benzyl can be iodinated with a suitable iodinating reagent (e.g., N-iodosuccinimide) in the presence of an acid (e.g., trifluoromethanesulfonic acid or TFA) in a manner similar to that described in Olah et al., *J Org. Chem.* 1999, 3194, or Castanet et al., *Tetrahedron. Lett.* 2002, 5047. See, e.g., Examples 71 and 72.

Scheme 10 depicts an alternative method for preparing naphthyridine carboxamide analogs embraced by the present invention in which the R⁵ substituent is other than H, starting from naphthyridine intermediate **10-1**. Hydrolysis of the pyridine **10-1** with a nucleophile such as hydroxide can afford the acid **10-2**, which can be coupled with an amine using a peptide coupling reagent such as BOP to afford amide **10-3**. Alternatively, **10-2** can be converted to the acid chloride using a suitable agent like thionyl chloride or oxalyl chloride/catalytic DMF, similar to the method described in Jerry

March, *Advanced Organic Chemistry*, 3rd edition, John Wiley & Sons, 1985, pp. 388, and the acid chloride treated directly with an amine to give the amide **10-3**. The intermediate **10-3** can then be treated with a suitable oxidizing agent (e.g., mCPBA or peracetic acid) to obtain the N-oxide **10-4**, which can then be treated as described Suzuki et al. *J. Med. Chem.* 1992, 35, 4045-4053 with acetic anhydride to effect the rearrangement to the O-acylated intermediate, and then treated with a nucleophile (e.g., an alkoxide such as NaOMe) to afford the desired dioxohexahydro-2,6-naphthyridine-1-carboxylate **10-5**. Intermediate **10-5** can be alkylated with an alkylating agent (e.g., an alkyl halide or an alkyl sulfate such as dimethyl sulfate) using a suitable base (e.g., an alkali metal carbonate such as K₂CO₃ or Cs₂CO₃, an alkali metal hydride such as NaH, or a metal alkoxide such as Mg(OMe)₂) in a solvent like DMSO to give a mixture of N- and O-alkylated products **10-6** and **10-7**. A similar use of alkali metal carbonates is described in T. Ukita, et.al. *Chem. Pharm. Bull.* 2000, 48 (4) 589-591.

SCHEME 10

Scheme 11 depicts a method for preparation of N-aryl or N-heterocyclyl naphthyridine carboxamides (see, e.g., Examples 25 to 53). The intermediate **11-1** can be prepared as described in Scheme 3 (see also Steps 1 to 6 of Example 12). The hydroxyl group on **11-1** can be protected as alkyl ether by treatment with a base (e.g., cesium carbonate, sodium hydride, or sodium bis(trimethyl)silylamide), followed by reaction with an alkylating reagent such as methyl iodide, benzyl bromide, using methods similar to those described in T. W. Greene & P. G. M. Wuts, Protective Groups in Organic Synthesis, 3rd edition, John Wiley & Sons, 1999, p. 246. The resultant naphthyridine intermediate **11-2** can then be converted to the corresponding naphthyridinone intermediate **11-3** in a sequence similar to that described in Steps 1 to 5 of Example 13. Naphthyridinone **11-3** can then be N-arylated with an appropriate aryl or heterocyclyl boronic acid in the presence of a catalyst such as copper(II) acetate (see Lam et al, *Tetrahedron Lett.* 1998, p. 2941, and references cited therein) and the resulting N-arylated compound treated with HBr in acetic acid or boron tribromide (see Scheme 2) to remove the ether protecting group and thereby provide **11-4**.

15 Scheme 11

Scheme 12 depicts a method for the preparation of N-aminoethyl naphthyridine carboxamides (see, e.g., Examples 66 to 68). The intermediate **12-1** can be alkylated with a dihaloalkane (exemplified by bromo-2-chloroethane in the scheme) using established alkylation conditions (e.g., in DMSO in the presence of magnesium methoxide as described in of Scheme 10) to provide the intermediate alkylation product **12-2a**. Treatment of **12-2a** with a suitable secondary amine in the presence of sodium iodide provides **12-3**. Similarly, **12-1** can be reacted with a Boc-protected haloalkyl

secondary amine (exemplified by 1-bromo-2-N-Boc-N-alkyl-aminoethane in the scheme) to provide **12-2b**, which can be treated with acid (e.g., HCl in dioxane) to provide the desired **12-4** (see T. W. Greene & P. G. M. Wuts, Protective Groups in Organic Synthesis, 3rd edition, John Wiley & Sons, 1999, p. 520).

5 Scheme 12

10 Scheme 13 depicts a method for preparation of naphthyridine sulfonamides (see, e.g., Examples 73 to 76). The carboxylic group in intermediate **13-1**, which can be prepared as described in Scheme 3, can be converted to the corresponding tert-butyl carbamate **13-2** via a Curtius rearrangement in the manner described in J. March, Advanced Organic Chemistry, 3rd edition, John Wiley & Sons, 1992, p. 1091 (e.g., acid **13-1** can be treated with diphenylphosphoryl azide in the presence of anhydrous

tert-butanol to afford carbamate **13-2**). Carbamate **13-2** can then be treated with base (e.g., as sodium hydride or sodium bis(trimethyl)silylamide), followed by contact with a sulfonylation reagent (e.g., an alkane sulfonyl chloride) to provide an intermediate sulfonylated carbamate, which can be transformed to the corresponding sulfonamide **13-3** by treatment with acid (e.g., TFA) in a manner similar to the conditions described in T. W. Greene & P. G. M. Wuts, Protective Groups in Organic Synthesis, 3rd edition, John Wiley & Sons, 1999, p. 520. Treatment of **13-3** with a base (e.g., sodium hydride or sodium bis(trimethyl)silyl-amide), followed by alkylation with a suitable reagent (e.g., an alkyl halide such as methyl iodide) and then by removal of the ether protecting group (see Schemes 2 and 11) to afford the desired **13-4**.

Scheme 13

Scheme 14 depicts the preparation of bromo compounds of the invention, wherein the carboxylic acid intermediate **14-1** (Scheme 9) is converted to the corresponding acid chloride by treatment with a suitable agent (e.g., oxalyl chloride or thionyl chloride) and the resulting acid chloride is converted to the corresponding bromide **14-2** via a Barton decarboxylative bromination as described in Barton et al, *Tetrahedron Lett.* 1985, 5939 (e.g., with a mixture of bromotrichloro-methane and 2-pyridinethiol-N-oxide in the presence of AIBN). The bromide **14-2** can then be converted to the corresponding naphthyridinone intermediate in a sequence similar to that described in Scheme 3. Subsequent removal of the ether protecting group (see description in Scheme 2 or Scheme 11) affords the desired **14-3**. N-alkylation of **14-3** provides **14-4**. Catalytic debromination of **14-3** and **14-4** (e.g., in the presence of 10% palladium on charcoal in methanol under an atmosphere of hydrogen similar to

conditions described in M. Freifelder, Catalytic Hydrogenation in Organic Synthesis Procedures and Commentary, John Wiley & Sons, 1978, p. 121) will afford analogs without a substituent in the 5-position of the naphthyridine ring.

5 Scheme 14

Scheme 15 depicts the preparation of alkylated products from a starting bromide, wherein bromide **14-4** is treated with an appropriate vinyl stannane in the presence of a palladium catalyst to provide the corresponding vinyl naphthyridine intermediate **15-1**. Hydrogenation or cyclopropanation of this intermediate, followed by removal of the ether protecting group, will afford the corresponding desired alkyl substituted naphthyridine **15-2** and cyclopropane substituted naphthyridine **15-3**.

Scheme 15

Compounds of the present invention having aryl, heteroaryl, or saturated heterocyclyl groups in the naphthyridine ring can be prepared by treatment of **14-4** with a saturated heterocycle or with an aryl/heteroaryl boronic acid or ester in the presence of a suitable ligand-complexed metal catalyst. Scheme 16 is illustrative, wherein the desired arylated analog **16-1** is obtained by treating **14-4** with an aryl boronic acid in the presence of a palladium catalyst (e.g., tetrakis(triphenylphosphine)-palladium(0)). Suitable chemistries are described in *Angew Chem Intl.* 2004, 1871; *Org. Lett.* 2003, 793; and *Tetrahedron Lett.* 2004, 3305.

Process P1 can produce Compound IV from Compound V in good yield without protecting the 4-hydroxy group. The P1 process is exemplified in Step 8 of Example 91, wherein the protection and deprotection steps included in the process set forth in Example 12 are avoided.

The Grignard salt employed in the P1 process is typically a halomagnesium salt of amine VI. The halomagnesium salt of amine VI is preferably a chloromagnesium salt or a bromomagnesium salt of amine VI, and is more preferably a chloromagnesium salt of amine VI (i.e., ClMgN(R^V)R^W).

Representative amines of Formula VI which can be employed in the P1 process include dimethylamine, diethylamine, isopropylethylamine, azetidine, pyrrolidine, piperidine, piperazine, 4-methylpiperazine, morpholine, and thiomorpholine.

The contacting step B of the P1 process is suitably conducted in an aprotic solvent. As used herein, the term "solvent" refers to an organic substance which is a chemically inert liquid under the reaction conditions and which will dissolve or suspend the reactants in such a manner as to bring the reactants into contact and permit the reaction to proceed.

Aprotic solvents suitable for use in the present invention include those selected from the group consisting of alkanes, cycloalkanes, halogenated alkanes, halogenated cycloalkanes, aromatic hydrocarbons, alkylated aromatic hydrocarbons, halogenated aromatic hydrocarbons, alkylated and halogenated aromatic hydrocarbons, ethers, polyalkylphosphoramides, N,N'-dialkylalkyleneureas, and mixtures thereof. In this context, a "halogenated" compound or substance is a compound or substance containing one or more C-H bonds wherein one or more of the hydrogens have been replaced with halogen. A class of solvents suitable for use in the P1 process consists of the solvents selected from the group consisting of C₁₋₁₀ linear and branched alkanes, C₁₋₁₀ linear and branched halogenated alkanes,

C₅-10 cycloalkanes, halogenated C₅-10 cycloalkanes, benzene, naphthalene, mono- and di- and tri-C₁-6 alkyl substituted benzenes, halogenated benzenes, halogenated mono- and di- and tri-C₁-6 alkyl substituted benzenes, dialkyl ethers wherein each alkyl is independently a C₁-6 alkyl, C₁-6 linear and branched alkanes substituted with two -O-C₁-6 alkyl groups (which are the same or different), C₄-C₈ cyclic ethers and diethers, phenyl C₁-4 alkyl ethers, diethylene glycol di(C₁-4 alkyl) ethers, hexa (C₁-6 alkyl)phosphoramides, N,N'-di-(C₁-6 alkyl)ethyleneureas, and N,N'-di-(C₁-6 alkyl)propyleneureas.

Representative examples of aprotic solvents suitable for use as a solvent in the P1 process include the following: pentane (individual isomers and mixtures thereof), hexane (individual isomers and mixtures thereof), heptane (individual isomers and mixtures thereof), cyclopentane, cyclohexane, cycloheptane, carbon tetrachloride, chloroform, methylene chloride, 1,2-dichloroethane, 1,1,2-trichloroethane, 1,1,2,2-tetrachloroethane, chlorocyclopentane, chlorocyclohexane, benzene, toluene, o- and m- and p-xylene, xylene mixtures, ethylbenzene, chlorobenzene, bromobenzene, o-chlorotoluene, 2,4-dichlorotoluene, 2,4,6-trichlorotoluene, ethyl ether, MTBE, THF, dioxane, 1,2-dimethoxyethane, HMPA, and DMPU.

In one embodiment of the P1 process, the contacting comprises adding Compound V to the Grignard salt of amine VI dissolved or suspended in the aprotic solvent to form a reaction mixture and ageing the reaction mixture. The Grignard salt can be prepared, for example, by adding amine VI dissolved or suspended in a first aprotic solvent to a solution of an alkylmagnesium halide (e.g., a C₁-4 alkylmagnesium chloride or bromide) in a second aprotic solvent that is the same or different from the first aprotic solvent. The addition can suitably be conducted with agitation (e.g., stirring) at a temperature at or below about 0°C (e.g., from about -50 to about 0°C, or from about -10 to about 0°C). The resulting admixture (either a solution or suspension) can then be aged with agitation for a time sufficient to effect formation of the amine salt, after which Compound V, typically dissolved or suspended in a third aprotic solvent that is the same or different from the first and second solvents, can be charged to the admixture (either maintained at a temperature below about 0°C -- e.g., from about -10 to about 0°C -- or warmed to a temperature in a range of from about 0 to about 25°C) to provide a reaction mixture, and the resulting reaction mixture is aged until the desired degree of conversion of Compound V is achieved or until conversion is complete.

As used herein, the term "ageing" and variants thereof (e.g., "aged") refer to maintaining the reactants in a given reaction or treatment step in contact for a time and under conditions effective for achieving the desired degree of conversion.

Process P1 can be conducted at any temperature at which the reaction forming Compound IV can be detected. The reaction (i.e., the contacting) can suitably be conducted at a temperature in a range of from about -40 to about 40°C, is typically conducted at a temperature in a range

of from about -20 to about 25°C, and is more typically conducted at a temperature in a range of from about -10 to about 0°C.

The Grignard salt of amine VI can be employed in any proportion with respect to Compound V which results in the formation of at least some of the desired compound of Formula IV, but the Grignard salt is typically employed in a proportion which, under the reaction conditions (e.g., temperature) employed, can optimize conversion of Compound V to Compound IV. The Grignard salt is suitably employed in an amount in a range of at least about 2 equivalents (e.g., from about 2 to about 10 equivalents) per equivalent of Compound V, is typically employed in an amount in a range of from about 3 to about 6 equivalents per equivalent of Compound V, and is more typically employed in an amount in a range of from about 4 to about 5 equivalents per equivalent of Compound V.

An embodiment of the P1 process is the process as originally defined above, wherein the compound of Formula IV is a compound of Formula IV-A:

the compound of Formula V is a compound of Formula V-A:

the Grignard salt is a Grignard salt of dimethylamine; X¹ is: (1) -H, (2) bromo, (3) chloro, (4) fluoro, or (5) methoxy; X² is: (1) -H, (2) bromo, (3) chloro, (4) fluoro, (5) methyl, (6) methoxy, (7) -CF₃, or (8) -OCF₃; and R⁵ is -C₁₋₄ alkyl.

Additional embodiments of the P1 process include the process as just described in the preceding embodiment incorporating one or more of the features (i) to (v) as follows:

- (ii) the contacting is conducted in an aprotic solvent selected from the group consisting of an alkane, a cycloalkane, a halogenated alkane, a halogenated cycloalkane, an aromatic hydrocarbon, an alkylated aromatic hydrocarbon, a halogenated aromatic hydrocarbon, an alkylated and halogenated aromatic hydrocarbon, an ether, a polyalkyl phosphoramidate, an N,N'-dialkylalkyleneurea, and mixtures thereof;
- (iii) the Grignard salt is $\text{ClMg}(\text{CH}_3)_2$;
- (iv) the contacting is conducted at a temperature in a range of from about -20 to about 25°C (e.g., in a range of from about -10 to about 0°C); and
- (v) the Grignard salt is employed in an amount of at least about 2 equivalents (e.g., in an amount in a range of from about 2 to about 10 equivalents, or from about 3 to about 6 equivalents, or from about 4 to about 5 equivalents) per equivalent of Compound V-A.

Another embodiment of Process P1 is the process as originally set forth above or as described in a preceding embodiment, which further comprises: (C) recovering Compound IV from the reaction medium. Compound IV can be recovered, for example, by quenching the reaction mixture with an aqueous solution of a mineral acid (e.g., aqueous HCl), separating the resulting organic layer (i.e., the aprotic solvent medium containing the desired product), and removing in whole or in part the volatile solvent from the organic layer using heat or a vacuum or both to obtain Compound IV either directly or by precipitation from the concentrated organic layer and separation of the precipitate by filtration.

Still another embodiment of the P1 Process is the process as originally set forth above which further comprises:

- (A) treating a compound of Formula IX:

with (i) a tertiary amine base in the presence of a lithium salt or (ii) an alkoxide base, to obtain a compound of Formula V; wherein one of bonds "c" and "d" is a single bond and the other is a double bond; R^{T*} is C₁₋₆ alkyl (where R^T and R^{T*} can be the same or different alkyl groups); and all other variables are as originally defined in the P1 process. In an aspect of this embodiment, Compound IX is a compound of Formula IX-A:

Compound V is a compound of Formula V-A as defined above; R^T and R^{T*} are each independently C₁₋₄ alkyl; and R⁵, X¹ and X² are each as defined in Compound V-A above. This embodiment of the P1 process (i.e., the embodiment including Steps A and B) is alternatively referred to herein as "Process P1a" or the "P1a process".

The tertiary amine bases suitable for use in the P1a process include trimethylamine, triethylamine, tri-n-butylamine, ethyl-diisopropylamine, N,N-dimethylaniline, N,N-dimethylbenzylamine, pyridine, picoline, N-methylpiperidine, N-methylmorpholine, 4-N,N-dimethylaminopyridine (DMAP), 1,4-diazabicyclo[2.2.2]octane (DABCO), 1,5-diazabicyclo[4.3.0]nonene (DBN), and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU).

Lithium salts suitable for use in the P1a process include halide salts and sulfonate salts, such as LiBr, LiCl, LiI, LiOTs, and LiOMs. A class of suitable lithium salts is the lithium halide salts, and a sub-class of suitable lithium halide salts is LiBr, LiCl, and LiI.

Alkoxide bases suitable for use in the P1a process include the alkali metal alkoxides such as the C₁₋₄ alkoxides of lithium, sodium and potassium. The alkoxide base can be, for example, LiOMe, NaOMe, NaOEt, KOMe, KOEt, t-BuONa, or t-BuOK.

Treating in Step A of the P1a process can suitably be conducted in an organic solvent. The organic solvent can be an aprotic solvent, wherein the aprotic solvent is suitably an ether, a tertiary amide, an N-alkylpyrrolidone, a sulfoxide, or an aromatic hydrocarbon. The solvent can be, for example,

THF, MTBE, DME, dioxane, DMF, DMAC, N-methylpyrrolidone, N-ethylpyrrolidone, DMSO, or toluene. A class of suitable solvents is the ethers (e.g., THF).

The treating in Step A of the P1a process can be conducted at any temperature at which the reaction forming Compound V can be detected. The treating can suitably be conducted at a temperature in a range of from about -20 to about 60°C, is typically conducted at a temperature in a range of from about 0 to about 30°C, and is more typically conducted at a temperature in a range of from about 15 to about 25°C.

The tertiary amine base (e.g., DABCO) or alkoxide base can be employed in Step A in any proportion with respect to Compound IX which results in the formation of at least some of the desired compound of Formula V, but the base is typically employed in a proportion which, under the reaction conditions (e.g., temperature) employed, can optimize conversion of Compound IX to Compound V. The base is suitably employed in an amount in a range of at least about 0.1 equivalent (e.g., from about 0.1 to about 5 equivalents) per equivalent of Compound IX, is typically employed in an amount in a range of from about 1 to about 5 equivalents per equivalent of Compound IX, and is more typically employed in an amount in a range of from about 2 to about 4 equivalents per equivalent of Compound IX.

The lithium salt (e.g., LiBr) used in combination with the tertiary amine base can be employed in Step A in any proportion with respect to Compound IX which results in the formation of at least some of the desired compound of Formula V, but salt is typically employed in a proportion which, under the reaction conditions (e.g., temperature) employed, can optimize conversion of Compound IX to Compound V. The Li salt is suitably employed in an amount in a range of at least about 0.1 equivalent (e.g., from about 0.1 to about 5 equivalents) per equivalent of Compound IX, is typically employed in an amount in a range of from about 1 to about 5 equivalents per equivalent of Compound IX, and is more typically employed in an amount in a range of from about 2 to about 4 equivalents per equivalent of Compound IX.

The treatment time can vary widely depending upon, *inter alia*, the scale of the treatment (e.g., laboratory bench v. pilot plant), the treatment temperature and the choice and relative amounts of reactants and reagents, but the reaction time is typically in a range of from about 15 minutes to about 24 hours.

In one embodiment, Step A of Process P1a comprises adding the Li salt (e.g., LiBr) to Compound IX dissolved or suspended in an organic solvent (e.g., an ether such as THF), and then adding the tertiary amine base (e.g., DABCO) to form a reaction mixture, and then ageing the resulting mixture to obtain Compound V. The additions of Li salt and amine base can be conducted with agitation (e.g., stirring). The reaction mixture is aged at a suitable reaction temperature as set forth above and optionally

with agitation until the desired degree of conversion of Compound IX is achieved or until conversion is complete. The addition of the Li salt and amine base to Compound IX can be done at the desired reaction temperature which is then maintained during ageing, or the addition of the Li salt and amine base can be done below the desired reaction temperature and the mixture brought to the desired temperature for ageing. The ageing can be quenched by addition of an acid. The desired Compound V can be recovered by extraction with a suitable organic solvent, followed by evaporative removal of the solvent.

25

The base employed in Process P2 can be a magnesium-containing base or a calcium-containing base. Magnesium and calcium bases suitable for use in the process include those of formula

M(R^X)₂, wherein M is Mg or Ca, and each R^X is independently H or -O-C₁₋₆ alkyl. Exemplary bases include MgH₂, Mg(OMe)₂, Mg(OH)₂, Mg(OEt)₂, MgHOMe, MgHOEt, CaH₂, Ca(OMe)₂ and Ca(OEt)₂. The base is preferably a magnesium base. In one embodiment, the P2 process is as originally set forth above, wherein the base comprises a magnesium base of formula Mg(R^X)₂ where R^X is as defined above. In an aspect of this embodiment, the base is a Mg(O-C₁₋₄-alkyl)₂. In another aspect of this embodiment, the base is Mg(OMe)₂.

The base can be employed in any proportion with respect to Compound VIII and alkylating agent (e.g., alkyl halide) which results in the formation of at least some of the desired N-alkylated compound of Formula VII, but the base is typically employed in a proportion which, under the reaction conditions (e.g., temperature) employed, can optimize conversion of Compound VIII to Compound VII. The base is suitably employed in an amount in a range of from about 0.5 to about 10 equivalents per equivalent of Compound VIII, is typically employed in an amount in a range of from about 1 to about 10 equivalents per equivalent of Compound VIII, and is more typically employed in an amount in a range of from about 1 to about 5 equivalents (e.g., from about 1.5 to about 2 equivalents) per equivalent of Compound VIII.

In one embodiment, the P2 process is as originally set forth above or as set forth in a preceding embodiment, wherein the alkylating agent is of formula R⁵-Z, wherein R⁵ is C₁₋₆ alkyl and Z is chloride, bromide, iodide, mesylate, or tosylate. In an aspect of this embodiment, Z is iodide or tosylate. In another aspect of this embodiment, the alkylating agent is MeI or methyl tosylate, and in a feature of this aspect the alkylating agent is methyl tosylate.

The alkylating agent can be employed in any proportion with respect to the base and Compound VIII which results in the formation of at least some of the desired N-alkylated compound of Formula VII, but the alkylating agent is typically employed in a proportion which, under the reaction conditions (e.g., temperature) employed will optimize conversion of Compound VIII to Compound VII. The alkylating agent is suitably employed in an amount in a range of from about 0.5 to about 20 equivalents per equivalent of Compound VIII, and is typically employed in an amount in a range of from about 1 to about 20 equivalents per equivalent of Compound VIII. The alkylating agent (e.g., alkyl halide) is more typically employed in an amount in a range of from about 1 to about 10 equivalents (e.g., from about 1 to 5 equivalents) per equivalent of Compound VIII. The alkylating agent is preferably employed in excess with respect to Compound VIII, such as in an amount in a range of from about 2 to

The solvent employed in Process P2 can be any polar aprotic solvent which under the conditions employed is in the liquid phase, is chemically inert, and will dissolve, suspend, and/or disperse the reactants so as to bring them into contact and permit the formation of the desired Compound VII. The solvent is preferably one which under the conditions employed in the process favors N-alkylation to the desired Compound VII over O-alkylation to an O-alkylated by-product. The polar aprotic solvent is suitably a halogenated alkane, an ether, an ester, a tertiary amide, an N-alkylpyrrolidone, a sulfoxide, or a nitrile; and is typically a tertiary amide, an N-alkylpyrrolidone, or a sulfoxide. In an aspect of this embodiment, the polar aprotic solvent comprises a N,N-di-(C₁₋₃ alkyl)-C₁₋₃ alkylamide, a N-(C₁₋₃ alkyl)pyrrolidone, or a di-(C₁₋₃ alkyl)sulfoxide. In another aspect of this embodiment, the polar aprotic solvent is DMF, DMAC, N-methylpyrrolidone, N-ethylpyrrolidone, or DMSO. In a feature of this aspect, the polar aprotic solvent is DMF.

Process P2 can be conducted at any temperature at which the reaction (N-alkylation) forming Compound VII can be detected. The reaction can suitably be conducted at a temperature in a range of from about -20 to about 100°C, is typically conducted at a temperature in a range of from about 0 to about 100°C, and is more typically conducted at a temperature in a range of from about 15 to about 80°C. In one embodiment of the P2 process the temperature is in a range of from about 20 to about 60°C, wherein the process step is initially conducted at about 20°C and subsequently heated to a temperature of about 60°C.

- 25 (i) the magnesium base comprises MgH₂ or Mg(O-C₁₋₃ alkyl)₂ (or is Mg(OMe)₂);
- (ii) the polar aprotic solvent is a N,N-di-(C₁₋₃ alkyl)-C₁₋₃ alkylamide, a N-(C₁₋₃ alkyl)pyrrolidone, or a di-(C₁₋₃ alkyl)sulfoxide (e.g., the solvent is DMF, DMAC, N-methylpyrrolidone, N-ethylpyrrolidone, or DMSO; or the solvent is DMF);
- (iii) the reaction is conducted at a temperature in a range of from about 0 to about
- 30 100 °C (or from about 20 to about 60 °C);

(iv) the alkylating agent R^5-Z is a C_{1-4} alkyl iodide or a C_{1-4} alkyl tosylate (or is MeI or methyl tosylate);

Another embodiment of Process P2 is the process as originally set forth above or as described in a preceding embodiment, which further comprises recovering Compound VII from the reaction medium. Process P2 can result in the formation of O-alkylated by-product, which can be
10 separated from the desired N-alkylated product (i.e., Compound VII) by methods known in the art such as washing the precipitated solids with suitable solvents or via chromatography.

The present invention also includes a process (alternatively referred to herein as "Process P3" or the "P3 process") for preparing a compound of Formula IV as defined above, which comprises treating a compound of Formula X:

with (i) a tertiary amine base in the presence of a lithium salt or (ii) an alkoxide base, to obtain a compound of Formula IV, wherein bonds "c" and "d" and R^{T*} are each as defined above in the P1a process; and all of the variables in Formula X are as originally defined above in the P1 process. An embodiment of the P3 process is the process as just defined, wherein the compound of Formula X is a
20 compound of Formula X-A:

the compound of Formula IV is a compound of Formula IV-A; and R^5 , X^1 and X^2 are each as defined in Compound IV-A above. The description of the choice and amounts of base (i.e., tertiary amine base or alkoxide base) and lithium salt, the treatment temperature, the treatment time, the choice and use of

organic solvents, methods of quenching and recovery, etc. set forth above for Step A of Process P1a applies to Process P3 as well and is considered part of the description of Process P3.

Process P2 is an alkylation process in which the R⁵ substituent is added to the ring nitrogen to provide the desired N-alkylated compound. Process P3, on the other hand, is a process in which cyclization of the ring affords the desired N-alkylated compound, the R⁵ substituent having been attached to the N atom prior to ring closure. (The R⁵ group can, for example, be introduced onto the N atom prior to cyclization by reductive amination with the appropriate aldehyde or ketone in the presence of a reducing agent such as a borohydride - see, e.g., Step 2 of Example 92.) When R⁵ is a bulky group (e.g., a branched alkyl group such as isopropyl or isobutyl), alkylation of the ring N can be sterically hindered resulting in relatively low yields of the desired compound VII in Process P2. In such cases (and where R^S is N(R^V)R^W), Process P3 can be preferred, because the cyclization is comparatively unaffected by the size of the R⁵ group and because methods for introducing R⁵ into the uncyclized precursor (e.g., reductive amination) can be more efficient relative to the post-cyclization alkylation of the P2 process.

It is understood that tautomers can exist for Compound IV in Process P1 and P3, Compound V in Process P1, and Compound VII and Compound VIII in Process P2 as a result of keto-enol tautomerism. The P1 and P2 and P3 processes encompass all tautomeric forms, individually and in mixtures.

The progress of any reaction step of any chemical process set forth herein, including processes P1 and P2 and P3, can be followed by monitoring the disappearance of a reactant (e.g., Compound VIII) and/or the appearance of the desired product (e.g., Compound VII) using such analytical techniques as TLC, HPLC, IR, NMR or GC.

Unless a contrary meaning is clear from the context, a reference herein to "equivalent" or "equivalents" means molar equivalent(s).

The following examples serve only to illustrate the invention and its practice. The examples are not to be construed as limitations on the scope or spirit of the invention. In the following examples "MS (M+1)" refers to the mass of the molecular ion plus 1 of the subject compound as determined by mass spectroscopy.

EXAMPLE 1

Step 1: 1-(4-Fluorobenzyl)piperidine-2-one

To a suspension of sodium hydride (2.4 g, 0.1 mol) in anhydrous THF (400 mL) was added piperidine-2-one (9.0 g, 90 mmol) in anhydrous THF (20 mL) over 10 minutes. After 20 minutes, the resultant thick slurry was treated with 4-fluorobenzyl bromide (18.9 g, 99.9 mmol). The reaction mixture was refluxed overnight. The resultant mixture was cooled to 0 °C and treated with H₂O (10 mL) cautiously. The mixture was stirred for 10 minutes and concentrated under vacuum. The residue was partitioned between ethyl acetate (300 mL) and H₂O. The organic extract was washed with brine, dried with MgSO₄, filtered, and concentrated under vacuum. The residual oil was subjected to column chromatography on silica gel eluting with 50 % - 70 % ethyl acetate in hexanes. The appropriate fractions were combined and concentrated to afford the benzylated piperidinone as a white solid. ¹H NMR (400 MHz, CDCl₃) δ 7.23 (dd, *J* = 8.7 Hz, 5.4 Hz, 2H), 7.00 (t, *J* = 8.7 Hz, 2H), 4.56 (s, 2H), 3.18 (t, *J* = 6 Hz, 2H), 2.46 (t, *J* = 6 Hz, 2H), 1.79 (m, 4H).

Step 2: 1-(4-fluorobenzyl)-3-(phenylsulfinyl)piperidin-2-one

To a cooled (0 °C) solution of 1-(4-fluorobenzyl)piperidine (5.0g, 24.1 mmol) in anhydrous THF (100 mL) was added lithium bis(trimethylsilyl)amide (1.0 M in THF, 53 mL, 53 mmol) dropwise, and the solution was stirred for one half hour. The solution was treated with methyl benzene sulfinic acid (5.65g, 36.1 mmol) in anhydrous THF (3 mL) dropwise. After 30 minutes at 0 °C, the resultant mixture was quenched with water and partitioned between 10% KHSO₄ and CHCl₃, the layers separated and the aqueous extracted several more times with CHCl₃. The organic extract was dried with Na₂SO₄, filtered, and concentrated under vacuum to afford 1-(4-fluorobenzyl)-3-(phenylsulfinyl)piperidin-2-one as a waxy solid that was taken on to the next step. Step 3: 1-(4-Fluorobenzyl)-5,6-dihydropyridin-2-(1*H*)-one

To a solution of 1-(4-fluorobenzyl)-3-(phenylsulfinyl)piperidin-2-one (0.37 g, 1.11 mmol) in toluene (15 mL) was added solid Na₂CO₃ (2g, 18.8 mmol). The reaction mixture was refluxed for about 6 hours. The resultant solution was filtered and concentrated under vacuum and the residue

chromatographed on silica eluting with a gradient of 0-40% EtOAc/Hexanes to give the product as colorless glass.

^1H NMR (400 MHz, CDCl_3) δ 7.26 (m, 2H), 7.01 (m, 2H), 6.56 (dt, $J=9.9$ Hz, 4.2 Hz, 1H), 6.00 (dt, $J=9.7$ Hz, 1.8 Hz, 1H), 4.59 (s, 2H), 3.32 (t, $J=7.2$ Hz, 2H), 2.33 (m, 2H).

Methyl oxalyl chloride (29.3 g, 0.24 mol) was carefully added dropwise. The reaction solution warmed to room temperature and stirred overnight. The product mixture was partitioned between H_2O and methylene chloride. The organic extract was dried with Na_2SO_4 and concentrated under vacuum to afford the title compound as a brown oil.

^1H NMR (400 MHz, CDCl_3) δ 7.59 (br, 1H), 4.14 (d, $J=5.6$ Hz, 2H), 3.93 (s, 3H), 3.79 (s, 3H). ES MS $M+1 = 176$

The reaction mixture was heated to 65 °C, then stirred overnight at room temperature. The product mixture was cooled to 0 °C and carefully quenched with ice and brine keeping the reaction from generating an unsuitable exotherm. The resultant mixture was extracted with ethyl acetate (600 mL). The organic extract was washed with brine, dried with Na_2SO_4 , then concentrated under vacuum. The residue was subjected to column chromatography on silica gel eluting with 100 % CH_2Cl_2 . The appropriate fractions were combined and concentrated to afford the title compound as a light yellow solid that was used without further purification.

In a sealed tube, 1-(4-fluorobenzyl)-5,6-dihydropyridin-2-(1H)-one (3.84 g, 18.7 mmol), and methyl 5-methoxy-1,3-oxazole-2-carboxylate prepared in Step 5 (2.94 g, 18.7 mmol), were combined. The reaction mixture was heated at 120 °C. After 24 hours, the resultant mixture was cooled and methanol saturated with HCl (2 mL) was added. The product mixture stirred at room temperature for

40 minutes, then was concentrated under vacuum. The residual crude material was diluted with DMSO (6.0 mL) and filtered to give the title compound.

The reaction mixture was heated to 100 °C for 1 hour. The product mixture was concentrated under vacuum and purified by reverse phase HPLC eluting with 5 % - 95 % acetonitrile (0.1 % TFA) in H_2O (0.1 % TFA) to afford the title compound as a yellow solid.

The reaction was cooled, the volatiles were removed under vacuum and the residue was dissolved in methylene chloride and washed with two 4L portions of water and dried over MgSO_4 . The next day the reaction was filtered, evaporated to give ~1.2 Kg of an oil that was chromatographed on silica eluting with Heptane/EtOAc to give product.

^1H NMR (400 MHz, CDCl_3) δ 7.56 (bs, 1H), 4.37 (q, $J = 7.2$ Hz, 2H), 4.2 (t, $J = 6.6$ Hz, 2H), 4.12 (d, $J = 5.5$ Hz, 2H), 1.64 (p, $J = 6.8$ Hz, 2H), 1.39 (t, $J = 7.15$ Hz, 3H), 1.37 (m, buried, 2H), 0.94 (t, $J = 7.4$ Hz, 3H) ppm. ES MS $M+1 = 232$.

Step 5: Ethyl 5-butoxy-1,3-oxazole-2-carboxylate

Butyl N-[ethoxy(oxo)acetyl]glycinate (783g, 3.38 mol) was dissolved in 8 L of acetonitrile in a 50L Chemglass reactor with overhead stirrer and P_2O_5 (415g, 2.92 mol) was added in large portions, watching for exotherm. The reaction was heated to 60 °C for 1 hour and LCMS showed the reaction done. After cooling, water (8L) was added at 20 °C and the reaction was transferred to a 50L

flask. Methylene chloride (8L) was added, the layers split and the aqueous layer was extracted with three 2L volumes of methylene chloride. The combined organic layers were washed with two 4L portions of saturated aqueous NaHCO₃, then dried with MgSO₄ and evaporated to give an oil that was purified on silica eluting with 0-30% EtOAc/heptane to give the product as an oil.

5 ¹H NMR (400 MHz, CDCl₃) δ 6.33 (s, 1H), 4.42 (q, *J* = 7.15 Hz, 2H), 4.18 (t, *J* = 6.4 Hz, 2H), 1.8 (p, *J* = 6.4 Hz, 2H), 1.47 (p, *J* = 7.4 Hz, 2H), 1.41 (t, *J* = 7.15 Hz, 3H), 0.97 (t, *J* = 7.4 Hz, 3H) ppm. ES MS *M*+1 = 214.

Step 6: Ethyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate

10 Ethyl 5-butoxy-1,3-oxazole-2-carboxylate (44.5g, 208.6 mmol) and 1-(3-chloro-4-fluorobenzyl)-5,6-dihydropyridin-2(1H)-one (25g, 104.3 mmol) were placed in a heavy walled round bottom flask equipped with a screw top and acid resistant O-ring and a stir bar. The mixture was stirred and water (2.82 mL, 156.7 mmol) was added. The reaction was sealed and placed in an oil bath pre-
15 heated to 130 °C. The reaction was aged for 72 hours, when LCMS showed much of the lactam had been consumed. The reaction was allowed to cool and sit until the mass had solidified. The mass was taken up in ether and the solids collected by filtration to give the product as a tan solid. The product was further purified by crystallization from EtOAc.

20 ¹H NMR (400 MHz, CDCl₃) δ 12.79 (s, 1H), 8.42 (s, 1H), 7.4 (dd, *J* = 2, 7Hz, 1H), 7.2 (m, 1H), 7.15 (t, *J* = 8.6 Hz, 1H), 4.7 (s, 2H), 4.4 (q, *J* = 7 Hz, 2H), 3.5 (m, 4H), 1.4 (t, *J* = 7 Hz, 3H) ppm. (ES MS *M*+1 = 379.0)

Step 7: Ethyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate 2-oxide

25 Ethyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate (22g, 58 mmol) was dissolved in 500 mL glacial acetic acid and H₂O₂ (30% by weight in water, 65.8 mL) was added. The reaction was warmed to 100 °C and aged for four hours at which time LCMS showed the reaction done. The solution was cooled in an ice bath to 25 °C and treated with saturated Na₂SO₃ solution, keeping the temperature below 40 °C. When starch paper test showed no
30 peroxides present, the solution was concentrated by 1/3, the pH was adjusted to ~3 with aqueous HCl and the solution extracted with CH₂Cl₂ several times. The organic layers were dried over Na₂SO₄, filtered and evaporated to give product as an oil.

¹H NMR (400 MHz, CDCl₃) δ 12.65 (s, 1H), 7.9 (s, 1H), 7.38 (dd, *J* = 2, 7Hz, 1H), 7.27-7.1 (m, 2H), 4.66 (s, 2H), 4.44 (q, *J* = 7 Hz, 2H), 3.52 (t, *J* = 7Hz, 2H), 2.90 (t, *J* = 7Hz, 2H), 1.38 (t, *J* = 7 Hz, 3H) ppm. (ES MS *M*+1 = 395.0)

5 Step 8: Ethyl 3,4-bis(acetyloxy)-6-(3-chloro-4-fluorobenzyl)-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate

 Ethyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate 2-oxide (23g, 58 mmol) was dissolved in 400 mL acetic anhydride and heated with stirring under nitrogen to 100 °C for 1 hour. By LCMS, the starting material and product are
10 very close in retention time. To check that the reaction was done, an aliquot was treated with NaOMe in water and CH₃CN. The resulting hydrolyzed product elutes at an earlier retention time and allows distinguishing between remaining N-oxide and rearranged product. The reaction was evaporated to give the crude product as an oily residue that was taken on to the next step.

¹H NMR (400 MHz, CDCl₃) δ 7.36 (m, 1H), 7.2-7.1 (m, 1H), 7.12 (t, *J* = 8Hz, 1H), 4.68 (bs, 2H), 4.4

Step 9: Methyl 6-(3-chloro-4-fluorobenzyl)-3,4-dihydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate

20 Ethyl 3,4-bis(acetyloxy)-6-(3-chloro-4-fluorobenzyl)-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate (27.8g, 58 mmol) was dissolved in 300 mL MeOH and treated with a 30% by weight solution of NaOMe in MeOH (41.8 mL, 232 mmol, 4 equivalents was sufficient to get the pH of the reaction to 9) for 5 hours at 40 °C. LCMS showed the cleavage of the acetate groups was complete, a little transesterification was observed as well. The volume was reduced by half under
25 vacuum and the mixture was diluted with THF (400 mL) and an additional 33mL of NaOMe was added. The reaction was stirred at room temperature overnight and then warmed to 50°C for four hours, when LCMS showed transesterification completed. The reaction was neutralized with 1N HCl and allowed to sit at room temperature overnight, then later acidified to pH 3 and extracted with CHCl₃ several times. The organic layer was dried over Na₂SO₄ and evaporated to give a black oil.

30 ¹H NMR (400 MHz, CDCl₃) δ 10.0-8.2 (bs, 1H), 7.38 (dd, *J* = 6.8. 2Hz, 1H), 7.2 (m, 1H), 7.13 (t, *J* = 8.4 Hz, 1H), 4.68 (s, 2H), 3.92 (s, 3H), 3.46 (t, *J* = 6.4 Hz, 2H), 3.34 (t, *J* = 6.4 Hz, 2H) ppm. (ES MS *M*+1 = 380.9)

Step 10: Methyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylate

To a solution of methyl 6-(3-chloro-4-fluorobenzyl)-3,4-dihydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate (18.00 g, 47 mmol) in DMF (200 mL) was added magnesium methylate (96.08 mL, 95 mmol), and the reaction was warmed for 1 hour and cooled. The reaction was treated with iodomethane (17.66 mL, 283 mmol) and stirred at 45 °C overnight. At this time, LCMS showed the reaction incomplete, and an additional equivalent of iodomethane (2.95 mL, 48 mmol) was added. The reaction was again stirred for 4 hours. The solvent was removed *in vacuo*, and the resulting oil was partitioned between chloroform and 1N HCl. The aqueous layer was washed twice more with chloroform. The organic fractions were extracted with 10% sodium bisulfite, and the bisulfite layer was washed twice with chloroform. The combined organic layers were washed with 5% aqueous HCl and brine, dried over sodium sulfate and concentrated *in vacuo* to afford the product as a black oil. This material appears quite clean by NMR and HPLC, but is highly colored.

¹H NMR (400 MHz, CDCl₃) δ 13.37 (s, 1H), 7.35 (dd, *J* = 2.4, 6.9 Hz, 1H), 7.22-7.18 (m, 1H), 7.13 (t, *J* = 8.4 Hz, 1H), 4.67 (s, 2H), 3.92 (s, 3H), 3.54 (s, 3H), 3.43 (t, *J* = 6.4 Hz, 2H), 2.81 (t, *J* = 6.4 Hz, 2H) ppm. (ES MS *M*+1 = 395.0)

Step 11: Methyl 6-(3-chloro-4-fluorobenzyl)-4-methoxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylate

To a solution of methyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylate (7.25 g, 18 mmol) in anhydrous DMF (75 mL) was added cesium carbonate (5.98 g, 18 mmol) and iodomethane (2.86 mL, 46 mmol). The reaction was stirred at room temperature overnight, and LCMS showed 70% completion. The reaction was heated to 50 °C for 7 hours and then allowed to stir at room temperature again overnight. LCMS indicated completion. The reaction was concentrated to dryness, and the resulting residue was dissolved in chloroform. The solution was extracted twice with saturated Na₂SO₃ solution, dried over sodium sulfate, filtered, and evaporated to afford a dark brown oil.

¹H NMR (400 MHz, CDCl₃) δ 7.34 (dd, *J* = 2.1, 7.0 Hz, 1H), 7.19 (m, 1H), 7.11 (m, 1H), 4.65 (s, 2H), 4.12 (s, 3H), 3.92 (s, 3H), 3.49 (s, 3H), 3.34 (m, 2H), 2.59 (m, 2H) ppm. (ES MS *M*+1 = 409.0)

Step 12: 6-(3-Chloro-4-fluorobenzyl)-4-methoxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylic acid

To a solution of methyl 6-(3-chloro-4-fluorobenzyl)-4-methoxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylate (14.3 g, 35 mmol) in THF (150mL) and MeOH

(150 mL) was added LiOH (2.74g, 114 mmol) dissolved in 114 mL water and the reaction was heated to 50 °C for 45 minutes. HPLC showed completion. The reaction was neutralized with 1N HCl and cooled to room temperature. THF was removed *in vacuo*, and the resulting slurry was partitioned between CHCl₃ and 5% aqueous HCl. The aqueous was washed with additional CHCl₃. The combined organics were dried over sodium sulfate, filtered, and concentrated to dryness to afford the desired product as a pale yellow foam. The material was crystallized from ethyl acetate to give a light yellow solid. ¹H NMR (400 MHz, CD₃OD) δ 7.49 (dd, *J* = 2.0, 6.8 Hz, 1H), 7.34-7.30 (m, 1H), 7.25-7.20 (m, 1H), 4.71 (s, 2H), 3.98 (s, 3H), 3.58 (s, 3H), 3.50 (m, 2H), 2.77-2.74 (m, 2H) ppm. (ES MS M+1 = 395.0)

10 Step 13: 6-(3-Chloro-4-fluorobenzyl)-4-methoxy-N,N,2-trimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide

To a suspension of 6-(3-chloro-4-fluorobenzyl)-4-methoxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylic acid (8.50 g, 22 mmol) in methylene chloride (300 mL) at 0 °C was added oxalyl chloride (2.25 mL, 26 mmol) and 1 drop of anhydrous DMF. The reaction was stirred at 0 °C for 15 minutes during which time no bubbling was observed. The reaction was then allowed to warm to room temperature and stirred for 40 minutes. At this time bubbling had ceased, and all material was in solution. An aliquot of the solution was quenched with dimethylamine and checked by LCMS to confirm completion. To the solution of the acid chloride starting material at 0 °C was added dimethylamine in THF (43.56 mL, 87 mmol, 2.0 M). The green/yellow reaction was allowed to stir at room temperature overnight although the reaction appeared to proceed immediately by LCMS. The solvent was removed *in vacuo*, and the resulting residue was dissolved in chloroform. The solution was washed with water and 5% aqueous HCl solution and back extracted to recover the product. The combined organic layers were washed with brine, dried over sodium sulfate, filtered and concentrated *in vacuo*. The resulting iridescent green/yellow residue was examined in several TLC solvent systems (95:5 CH₂Cl₂:MeOH, 2:1 acetone:hexanes, 1:1 EtOAc:hexanes) with the most efficient separation of some early running impurities achieved in the CH₂Cl₂:MeOH system. The material was purified by silica gel flash column chromatography, loaded as a solution in methylene chloride onto a 330 g RediSep column. Gradient elution consisted of 1.5 L each of neat CH₂Cl₂, 1% MeOH:CH₂Cl₂, 2% MeOH:CH₂Cl₂, 3% MeOH:CH₂Cl₂, 4% MeOH:CH₂Cl₂, and 5% MeOH:CH₂Cl₂, in sequential order. The desired material began to elute with 3% and was pushed off the column with 4% and 5%, yielding two sets of fraction. The earlier set afforded of the desired product plus a fluorescent green contaminant. The later set afforded clean material.

¹H NMR (400 MHz, CD₃OD) δ 7.49 (dd, *J* = 2.0, 7.2 Hz, 1H), 7.34-7.31 (m, 1H), 7.22 (t, *J* = 8.8 Hz, 1H), 4.77 (d, *J* = 15.2 Hz, 1H), 4.65 (d, *J* = 15.2 Hz, 1H), 3.97 (s, 3H), 3.52-3.48 (m, 2H), 3.45 (s, 3H), 3.11 (s, 3H), 2.97 (s, 3H), 2.57-2.54 (m, 2H) ppm. (ES MS *M*+1 = 422.0)

5 Step 14: 6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N,2-trimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide

To 6-(3-chloro-4-fluorobenzyl)-4-methoxy-N,N,2-trimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide (5.43 g, 13 mmol) was added 33% HBr in acetic acid (20 mL, 129 mmol), and the mixture was heated to 50 °C for 15 minutes to give a thick, pale brown/orange solution. By LCMS, the reaction was complete, and the acetic acid was removed *in vacuo*. The resulting residue was partitioned between chloroform and water, and the organic layer was then washed with aqueous sodium sulfite solution and brine. The combined organic extracts were dried over sodium sulfate, filtered, and concentrated *in vacuo* to afford a pale yellow foam. The foam was dissolved in hot isopropanol and crystallized quickly, and the crystals were collected by filtration. The material was then taken up in hot acetone which did not afford a complete solution, so the mixture was hot filtered. The resulting filtrate was allowed to cool causing crystals to form. The insoluble material from the hot acetone filtration was dissolved in hot ethanol and re-filtered. This resulting filtrate also produced large, slowly grown crystals over the course of one day. The crystals compound free base from both filtrates were collected, combined, dried for 4 hours, milled, and re-dried overnight without heat to give product.

10 ¹H NMR (400 MHz, CD₃OD) δ 7.51 (dd, *J* = 2.1, 7.2 Hz, 1H), 7.36-7.33 (m, 1H), 7.23 (t, *J* = 8.9 Hz, 1H), 4.79 (d, *J* = 14.8 Hz, 1H), 4.65 (d, *J* = 14.8 Hz, 1H), 3.52 (t, *J* = 6.8 Hz, 2H), 3.46 (s, 3H), 3.10 (s, 3H), 2.97 (s, 3H), 2.64 (t, *J* = 6.8 Hz, 2H) ppm. (ES MS exact mass = 408.1113)

25 Step 15: 6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N,2-trimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide sodium salt

To 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-N,N,2-trimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide (1.08g, 2.65 mmol) in a freeze drying flask was added acetonitrile (5 mL) at room temperature. The flask was placed in an ultrasonic bath at room temp for 1 minute. Some crystals remained. Water was added (5 mL) followed by the 1 N NaOH (2.65 mL, 2.65 mmol). The total was placed in the ultrasonic bath for 1 minute. An additional 1 mL of acetonitrile was added and placed in the ultrasonic bath for an additional minute. All material was now dissolved. More water (30 mL) was added to the flask and all stayed soluble. The contents of the flask were frozen with spinning in a -78 °C acetone /dry ice bath and placed on the freeze drier for 40 hours to give the product as a dry fluffy solid.

EXAMPLE 13

6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-2-isopropyl-N,N-dimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide

10 Step 1: 6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylic acid

To a solution of ethyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate (27.0 g, 71 mmol) in THF (333 mL) and MeOH (166 mL) was added LiOH (5.21 g, 214 mmol) dissolved in enough water to make a 1N solution (total volume 213 mL) and the reaction was heated to 60 °C overnight. HPLC showed completion. A white precipitate was observed. The reaction was neutralized with 1N HCl and the more volatile solvents removed, leaving the water solution. 300 mL water was added the solution was acidified to pH 1 with 1 N HCl. A large amount of solids had precipitated. The resulting slurry was stirred vigorously with 100 mL CHCl₃. Most of the solid had precipitated from the partitioning and the entire mix was filtered and dried over the weekend to give product. Additional less pure product was recovered from extraction of the filtrate.

15 ¹H NMR (400 MHz, CD₃OD) δ 8.25 (s, 1H), 7.53 (dd, *J* = 2.2, 6.9 Hz, 1H), 7.36 (m, 1H), 7.23 (t, *J* = 8.9 Hz, 1H), 4.74 (s, 2H), 3.61 (bt, *J* = 6.4 Hz, 1H), 3.50 (bt, *J* = 6.4 Hz, 1H) ppm. (ES MS *M*+1 = 351.0)

25 Step 2: 6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N-dimethyl-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxamide

To a suspension of 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylic acid (25.0 g, 71.3 mmol) in methylene chloride (1000 mL) at 0 °C was added oxalyl chloride (12.4 mL, 143 mmol) and 8 drops of anhydrous DMF. The reaction was stirred at 0 °C for 15 minutes. during which time no bubbling was observed. The reaction was then allowed to warm to

room temperature and stirred for 40 minutes. At this time bubbling had ceased. An aliquot of the solution was quenched with dimethylamine and checked by LCMS. The reaction was incomplete. An additional 0.5 equivalent of oxalyl chloride was added and the reaction stirred an additional 40 minutes. The reaction never attained complete solution but was complete by LCMS. To the suspension of the acid chloride cooled to 0 °C was slowly added 2M dimethylamine in THF (140.8 mL, 281 mmol). The rate of addition was adjusted to avoid a large exotherm. The pH of the solution was found to be about 9. The yellow reaction was allowed to stir at room temperature overnight although the reaction appeared to proceed immediately by LCMS. The solvent was removed *in vacuo*, and the resulting residue was dissolved in chloroform. The solution was washed with water and 5% aqueous HCl solution and the aqueous layer back extracted to recover the product. The combined organic layers were washed with brine, dried over sodium sulfate, filtered and concentrated *in vacuo* to give a brown/yellow waxy solid. The initial NMR shows an excessive number of methyl group peaks, perhaps as a result of oxalyl chloride reacting with dimethylamine. A small sample was purified by reverse phase chromatography eluting with 95:5-5:95 water/acetonitrile 0.1% TFA to give clean material for NMR.

¹H NMR (400 MHz, CDCl₃) δ 12.35 (bs, 1H), 10.9 (bs, 1H), 8.32 (s, 1H), 7.38 (dd, *J* = 2.0, 6.7 Hz, 1H), 7.22 (m, 1H), 7.14 (t, *J* = 8.5 Hz, 1H), 4.69 (s, 2H), 3.54 (t, *J* = 6.8 Hz, 2H), 3.14 (s, 3H), 3.05 (t, *J* = 6.8 Hz, 2H), 2.95 (s, 3H) ppm. (ES MS *M*+1 = 378.1)

Step 3: 6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N-dimethyl-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxamide 2-oxide

6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N-dimethyl-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxamide (24g, 63.5 mmol) was dissolved in 1000 mL glacial acetic acid and peracetic acid (32% by weight in acetic acid, 151 mL, 635 mmol) and sodium acetate (2.6g, 31.7 mmol) was added. The reaction was warmed to 50 °C and aged overnight at which time LCMS showed the reaction done. The solution reduced in volume to 1/3 on the rotoevaporator, cooled in an ice bath and quenched slowly with 10% Na₂SO₃ solution until no peroxide was detected by a starch paper test. The reaction was transferred to a separatory funnel and water (500mL) and chloroform was added. The layers were separated and the water extracted with CHCl₃ several times. The combined organic layers were washed with slightly acidic water, brine and dried over Na₂SO₄, filtered and evaporated to give the product as an oil. The initial NMR shows an excessive number of methyl group peaks, perhaps as a result of oxalyl chloride reacting with dimethylamine in the second step and this impurity being carried through. A small sample was purified by reverse phase chromatography eluting with 95:5-5:95 water/acetonitrile 0.1% TFA to give clean material for NMR.

- 6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N-dimethyl-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxamide 2-oxide (25g, 63.5 mmol) was dissolved in 24 mL acetic anhydride and heated with stirring under nitrogen to 100°C for 16 hours. By LCMS, the starting material and product are close in retention time and appear as the same molecular weight. To check that the reaction was done, an aliquot was treated with NaOMe in water and CH₃CN. The resulting hydrolyzed product elutes at an earlier retention time and allows distinguishing between remaining N-oxide and rearranged product. The reaction was evaporated and the residue was partitioned between chloroform and water and the water layer was back-extracted with more chloroform. The aqueous layer was checked by LCMS for product and no longer contained any. The organic layers were combined, dried over Na₂SO₄, filtered and evaporated to give an oil. (ES MS *M*+1 of NaOMe treated aliquot = 394.0)

- Step 5: 6-(3-Chloro-4-fluorobenzyl)-3,4-dihydroxy-N,N-dimethyl-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxamide
- 20 6-(3-Chloro-4-fluorobenzyl)-1-[(dimethylamino)carbonyl]-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-3,4-diyl diacetate (30g, 62.7 mmol) was dissolved in 500 mL MeOH and treated with a 30% by weight solution of NaOMe in MeOH (45.2 mL, 251 mmol 4 equivalents was sufficient to get the pH of the reaction to 9) for 1 hour at 40 °C. LCMS showed the cleavage of the acetate groups was complete. The reaction was neutralized with 1N HCl and the volume reduced to remove the MeOH and the residue was diluted with water and acidified to pH 3. The cloudy aqueous layer was diluted with an equal volume (800 mL) of chloroform. After shaking, the product began to crystallize out of the solutions and gathered at the meniscus. The total contents of the funnel were filtered and the collected solids were washed with water until no more salts appeared to remain. The solid was dried *in vacuo* for 16 hours to give a cinnamon colored solid. The organic layer from the filtered extraction was collected, washed with water and dried over Na₂SO₄, filtered and evaporated. The residue was crystallized from methanol to give product. The crude material was quite insoluble but was crystallized from DMF, then boiled in MeOH, filtered and dried under vacuum to give product.

To a solution of 6-(3-chloro-4-fluorobenzyl)-3,4-dihydroxy-N,N-dimethyl-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxamide (3.00 g, 7.62 mmol) in DMSO (86 mL) was added magnesium methylate (42.75 mL of a 6-10% methanol solution, 24.4 mmol), and the reaction was heated to 60 °C for 0.75 hour. The reaction mixture was reduced on a rotoevaporator to remove all of the MeOH over 45 minutes. The heat gun was used to drive all MeOH from the bump bulb. The reaction was treated with 2-iodopropane (2.84 mL, 38.1 mmol) and allowed to stir at 60 °C for 3 hours. LCMS showed 11% starting material remaining and over 70% conversion to N- and O-alkylated products (typically 2:1). The reaction was diluted with 350mL EtOAc to which 125 mL 1N HCl was added, and the phases were separated. The aqueous layer was washed once with methylene chloride (100 mL). The combined organic layers were washed with 1N HCl twice more and the organic layer was isolated. The organic layer was washed with 10% aqueous solution of NaHSO₃ (3x 100 mL) followed by brine. The organic layer was dried over sodium sulfate and concentrated *in vacuo* to afford a yellow-orange foam residue. The solid combined with additional crude material from other reactions, dissolved in DMSO and Methanol and purified via reverse phase chromatography using a Biotage 75L canister and a Varian Metaflash 75L C-18 column, eluting with a gradient of 70:30 to 35:65 A:B where A= 0.05% TFA in water and B = 0.05% TFA in acetonitrile (flowrate = 300 mL/minute, detection at 214 and 254 nM). Evaporation of the fractions afforded pure oil by HPLC/LCMS and NMR. Crystallization from EtOAc:hexane afforded white, analytically pure product.

compounds of the present invention exhibit inhibition of HIV replication in this assay. For example, the compounds in Examples 1-15, 17-71, and 73-87 were found to have IC₉₅'s equal to or less than about 10 micromolar in the present assay.

EXAMPLE 91

6-(3-Chloro-4-fluorobenzyl)-4-hydroxy-N,N,2-trimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide

Step 1: 1-(3-Chloro-4-fluorobenzyl)piperidin-2-one

Valerolactam (60 g) was dissolved in MTBE (1.5L) at room temperature. To this solution was added Bu₄NSO₄ (4.9 g) as a phase transfer catalyst. The cloudy solution was stirred at room temperature for 5 minutes. Then, NaOH (50 wt%; 300 mL) was slowly added as to keep the internal temperature below 30°C. 3-Chloro-4-fluorobenzyl bromide (108.3 g) was then added slowly to this biphasic mixture, again as to keep the internal temperature under control. The reaction was then aged for 4 hours at room temperature. At this time LC showed the reaction to be complete. Water (500 mL) was then added. After phase cut, the organic layer was washed with brine (300 mL), dried under MgSO₄ followed by solvent switch to heptane (400 mL). The slurry obtained was stirred at room temperature for 1 hour and then filtered to afford the title product.

Step 2: Preparation of an unsaturated sulfide of formula **1**:

1-(3-Chloro-4-fluorobenzyl)piperidin-2-one (25g) was dissolved in THF (250 mL) and cooled to -20 degrees C under nitrogen atmosphere. LHMDs (204 mL, 1M in THF) was added over 40 minutes at -20 to -30°C and aged for 1 hour at -20°C. Methyl benzene sulfinat (17.78 g) was added over 30 minutes, again keeping the internal temperature at -20°C. The reaction was aged for 30 minutes at -20°C at which time LC showed the reaction to be complete. The reaction mixture was then quenched with water (100 mL) and diluted with EtOAc (300 mL). After phase cut, the organic layer was washed with HCl 2N (2 x 100 mL). The organic layer was then washed with brine (2 x 100 mL), dried under MgSO₄ followed by solvent switch to DCM (600 mL; final volume 400 mL). To this solution was added acetic anhydride (11.6 mL) and MeSO₃H (3.07 mL). The solution was then aged at room temperature overnight. The reaction was quenched with water (300 mL) and cooled to 0°C. The slurry obtained was then carefully basified to pH=8 with solid Na₂CO₃. The organic layer obtained after phase cut was then

washed with brine and dried under MgSO_4 . After evaporation of solvents, the title unsaturated sulfide 1 was obtained as an oil which solidified on standing. The title sulfide 1 can be crystallized from MeOH.

Step 3: Preparation of a vinyl sulfoxide of formula 2:

- 5 Unsaturated sulfide 1 (35.47 g) was dissolved in MeOH (200 mL) and water was added (50 mL) followed by the addition of solid NaIO_4 (39.82 g). The slurry obtained was stirred at room temperature for 3 days. The slurry was then filtered and the solid obtained was washed with EtOAc (200 mL). The filtrate was then evaporated until almost dryness and diluted with EtOAc (350 mL) and washed with H_2O (200 mL). The organic layer was then washed with brine (200 mL) and dried under MgSO_4 .
- 10 The organic solvents were then removed to completion. The oil obtained was crystallized with a IPAc:Hexane (1: 1.2) mixture and seeding to afford the title sulfoxide 2.

Step 4: Preparation of a Michael adduct of formula 3:

- 15 To a solution of vinyl sulfoxide 2 (5g, 13.74 mmoles) in THF (70 mL) at 0°C was added diphenylketimine glycine ethyl ester (4g, 15. mmoles) followed by t-BuOLi (0.2g, 2.5 mmoles). The mixture was stirred for 20 minutes at 0°C then, HCl 2N (80 mL) was added. The resulting mixture was stirred at 20°C for 20 minutes and MTBE (160 mL) was added. After phase separation, the aqueous layer was basified to pH=8-9 by addition of solid Na_2CO_3 . The resulting aqueous layer was extracted twice with EtOAc (2x100 mL) and the solvent evaporated under reduced pressure to give the title adduct 3 as
- 20 an oil.

Step 5: Preparation of an oxamate of formula 4:

- 25 To a solution of adduct 3 (6.2g, 13.28 mmoles) in THF (70 mL) at 0°C was added triethylamine (2 mL, 14.6 mmoles) followed by dropwise addition of ethyloxalyl chloride (1.55 mL, 13.94 mmoles). The resulting slurry was stirred for 20 minutes at 0°C , then water (50 mL) was added. The mixture was extracted with EtOAc (2x100 mL), then solvent switched to toluene (final volume: 80 mL). The toluene solution was heated to 90°C for 30-45 minutes then passed through a plug of silica gel

(50g) using EtOAc/hexanes 1:1 (200 mL), then EtOAc as eluent. After evaporation of the solvents, the title oxamate 4 was obtained.

Step 6: Ethyl 6-(3-chloro-4-fluorobenzyl)-3,4-dihydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate

To a solution of oxamate 4 (2g, 4.5 mmol) in THF (35 mL) was added LiBr (1.2g, 18.1 mmol) followed by DABCO (0.76g, 6.8 mmol). The mixture was stirred for 18 hours at 20°C, then HCl 2N (50 mL) was added and the mixture was extracted with EtOAc (50 mL). Solvents were evaporated under reduced pressure to give the title compound as a pale yellow solid.

Alternative Route:

Ethyl 6-(3-chloro-4-fluorobenzyl)-3,4-dihydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate

To a stirred solution of ethyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate (5.0 g; see Example 12, Step 6) and sodium acetate (0.89 g) in acetic acid (90 mL) was added peracetic acid (28 mL). The mixture was then heated at 50°C overnight. The mixture was cooled to 5°C and saturated NaHSO₄ (17 mL) added, keeping the temperature at less than 25°C. The mixture was concentrated to 50% original volume and partitioned between tert-butyl methyl ether (100 mL) and water (50 mL). The organic phase collected and the volatiles evaporated. The residue was dissolved in toluene (50 mL) and volatiles evaporated, the residue dissolved in toluene (50 mL) and evaporation repeated. Finally the residue was dissolved in toluene (20 mL). Acetic anhydride (3.9 mL) was added and the mixture heated at reflux until complete by HPLC analysis. The mixture cooled to ambient temperature and sodium ethoxide in ethanol (20 mL) was added. The reaction mixture stirred overnight. 2N HCl (31 mL) was added and the title product isolated by filtration.

Step 7: Methyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylate

To a stirred suspension of ethyl 6-(3-chloro-4-fluorobenzyl)-3,4-dihydroxy-5-oxo-5,6,7,8-tetrahydro-2,6-naphthyridine-1-carboxylate (40g) in DMF (200 mL) was added magnesium methoxide in methanol (100 mL). The mixture heated at 40-50°C for 3 hours. The excess methanol

distilled off, and methyl tosylate (18 mL) was added. The reaction mixture was heated at 50°C overnight, then cooled to 25°C, and then quenched into 1N HCl (100 mL). The suspension stirred for 1 hour at ambient temperature. The product was isolated by filtration, and the filter cake washed with water (2 x 100 mL) and then dried on the filter under an atmosphere of nitrogen. The crude product was suspended

in methanol (460 mL), heated at reflux temperature for 1 hour, and then allowed to cool to ambient temperature. The product was isolated by filtration and the filter cake washed with cold methanol (2x 40 mL) and dried to give the title product.

To THF (80mL) cooled to -10°C was added iPrMgCl (2M in THF, 60 mL).

Dimethylamine (2M in THF) was then added at -10 to 0°C, the mixture then stirred for 1 hour at -5 to -10°C. The resulting suspension of ClMgNMe₂ at -10°C was allowed to warm to 0°C, and a solution of methyl 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-2-methyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxylate (10.0 g) in dichloromethane (100 mL) was added over 20 minutes at 0°C. The mixture was stirred for 20 minutes at 0°C, and then HCl 2N (80 mL) was added. The resulting mixture was stirred at 20°C for 20 minutes and MTBE (160 mL) was added. After phase separation, the aqueous layer was basified to pH=8-9 by addition of solid Na₂CO₃. The resulting aqueous layer was extracted twice with EtOAc (2x100 mL) and the solvent evaporated under reduced pressure to give the title adduct as an oil.

Step 2: Preparation of an isopropyl amine of formula **6**:

To a solution of adduct **5** (2.5g, 5.35 mmol) in MeOH (30 mL) was added acetone (0.8 mL, 10.7 mmol) followed sodium triacetoxymethylborohydride (1.2g, 5.9 mmol). The mixture was stirred for 20 minutes, and then water (10 mL) and NaHCO₃ saturated (30 mL) were added. The resulting mixture was extracted twice with EtOAc (2x30 mL) and the solvent evaporated under reduced pressure to provide the crude title product.

Step 3: Preparation of an oxamate of formula **7**:

Crude amine **6** (5 mmol) is dissolved in THF (40 mL) at 0°C and triethylamine (1.4 mL, 2.2 eq.) was added followed by dropwise addition of ethyloxalyl chloride (1 mL, 2.1 eq.). The resulting slurry was stirred for 20 minutes at 0°C, then water (30 mL) was added. The mixture was extracted with EtOAc (2x40 mL), then solvent switched to toluene (final volume: 20 mL). The toluene solution was heated at 90°C for 30-45 minutes then passed through a plug of silica gel (20g) using EtOAc/hexanes 1:1 (200 mL), then EtOAc as eluant. EXAMPLE 93

- 5 Crystalline sodium salt of 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-2-isopropyl-N,N-dimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide

Part A: Preparation

- 10 MeOH (10 mL) and MTBE (50 mL) were added to 6-(3-chloro-4-fluorobenzyl)-4-hydroxy-2-isopropyl-N,N-dimethyl-3,5-dioxo-2,3,5,6,7,8-hexahydro-2,6-naphthyridine-1-carboxamide (6.94 g). NaOH/MeOH (1 N; 15.95 mL) was then charged thereto, and the admixture stirred until the carboxamide dissolved. The solution was filtered and additional MTBE (65 mL) was added to the filtrate. The filtrate was concentrated by removal of MeOH under vacuum (190 mm Hg at 40°C). The resulting concentrate (140 mL) was seeded, heated to 40°C, and aged overnight. The aged concentrate
15 was then cooled to room temperature, and the resulting solids were separated by filtration, washed with 10% MeOH/MTBE, and vacuum dried at room temperature to afford a crystalline sodium salt.

Part B: Characterization

- 20 An XRPD pattern of a Na salt prepared in the manner described in Part A was generated on a Philips Analytical X'Pert Pro X-ray powder diffractometer using a continuous scan from 2.5 to 40 degrees 2 Θ . Copper K-Alpha 1 ($K_{\alpha 1}$) and K-Alpha 2 ($K_{\alpha 2}$) radiation was used as the source. The experiment was run under ambient conditions. 2 Θ values and the corresponding d-spacings in the XRPD pattern include the following:

Peak No.	d-spacing (Å)	2 Theta
1	15.0	5.9
2	8.1	10.9
3	7.1	12.5
4	6.6	13.3
5	5.7	15.5
6	5.0	17.6
7	4.7	18.7
8	4.2	21.3
9	3.7	23.9

A Na salt prepared in the manner described in Part A was also analyzed by a TA Instruments DSC 2910 differential scanning calorimeter at a heating rate of 10°C/min from room temperature to 250°C in a closed pan in a nitrogen atmosphere. The DSC curve exhibited an endotherm with a peak temperature of 220°C and an associated heat of fusion of 27 J/gm. The endotherm is believed to be due to melting.

A thermogravimetric analysis was performed with a Perkin-Elmer Model TGA 7 under nitrogen at a heating rate of 10°C/min from room temperature to 250 °C. The TG curve showed a 1.1 % weight loss from 20 to 220 °C.
